

Chlorophenol Aquatic Life Water Quality Standards

Schedule 6 of the Contaminated Sites Regulation provides aquatic life water quality standards for chlorophenols. These standards consist of a range of legally allowable concentrations at 20 °C for a pH range of 5.7–9.2, for all chlorophenol classes:

- monochlorophenols
- dichlorophenols
- trichlorophenols
- tetrachlorophenols
- pentachlorophenol

As noted in footnote 41 of the schedule, the standards vary with pH, temperature, and substance isomer.

This technical guidance document presents the advice of the Director of Waste Management and explains how to select applicable aquatic life water quality standards for these substances.

Dependence on pH, temperature, and isomer

Typically, chlorophenol aquatic toxicity increases with:

- increasing chlorination,
- increasing water temperature, and
- decreasing pH.

This has important implications for pollution prevention, because water temperature is subject to seasonal variation and pH can change from location to location.

The Schedule 6 *minimum* standard for each chlorophenol class was selected for the most toxic isomer within each class, a temperature of

20 °C, and a pH of 5.7–6.1. The *maximum* standard for each chlorophenol class is based on a temperature of 20 °C, the toxicity of the least toxic isomer within a class, and a pH of 9.2 or greater.

Under some circumstances, such as a temperature lower than 20 °C, chlorophenol concentrations in excess of the maximums listed in Schedule 6 are acceptable.

Director's advice

The Schedule 6 chlorophenol aquatic life standards may be derived in two ways.

Option 1. Direct comparison with minimum Schedule 6 chlorophenol standards

At sites for which the aquatic life water quality standards apply, if the total concentration of a chlorophenol class does not exceed its minimum standard, then the site meets that standard.

Example:

Schedule 6 provides the following aquatic life standards for monochlorophenols: 8.5–650 ug/L.

Thus, at any site where the monochlorophenol aquatic life protective standards are applicable, the site is not considered a contaminated site if the total concentration of monochlorophenols present in water does not exceed 8.5 ug/L. The site would not require further remediation if it had already been cleaned up.

Note that since the Schedule 6 minimum standard represents the most conservative

combination of isomer, pH, and temperature variables, there is no need to measure concentrations of the specific chlorophenol isomers for that class or to determine the pH or temperature of the water.

Option 2. Comparison with temperature, pH and isomer-specific standards for chlorophenols

Where the concentrations of individual isomers within a chlorophenol class are known, as is the water pH and temperature, Tables 1-5 (attached) may be consulted to establish the appropriate chlorophenol aquatic life water quality standards for the site.

Note: If a person wishes to use the tables, concentrations of all listed chlorophenol isomers, water pH, and temperature must be measured at the site.

Since chlorophenol toxicity increases with temperature, ministry staff need to be assured that this parameter has been measured during at the warmest season of the year. Similar requirements pertain to the

appropriate determination of water pH and chlorophenol isomer concentrations at the site, if they vary seasonally.

A Director of Waste Management may require additional characterization related to chlorophenol contamination. People seeking to use the attached tables for their site should contact the Director for further advice.

Example:

Groundwater adjacent a former wood treatment site contains 138 ug/L of 2,4,5-trichlorophenol. The summertime groundwater temperature was 8.0°C, and the pH was 6.8. The applicable standard is obtained from Table 2, which applies to temperatures of 5.0-9.5 °C. The fourth column from the left contains standards for a pH of 6.8, and the value for 2,4,5-trichlorophenol is 18 ug/L. The observed concentration of 138 ug/L exceeds the 18 ug/L standard.

For more information, contact the Environmental Management Branch at site@gov.bc.ca

**Isomer, pH, and Temperature-Specific Tables
for Contaminated Sites Aquatic Life Water Quality Standards for Chlorophenols**

In accordance with the Contaminated Sites Regulation, Schedule 6, footnote 41, aquatic life protective water quality standards for chlorophenols can vary with pH, temperature, and substance isomer. Tables 1-5 constitute the advice of the Director of Waste Management regarding the appropriate aquatic life protective water quality standards to use for chlorophenols.

Notes:

1. The following tables may only be used if measured values of isomer concentrations, water pH, and temperature are known for the site.
2. Water temperature should be measured to the nearest 0.5 °C.
3. Water pH should be measured to the nearest 0.1 pH unit.
4. Chlorophenol isomer concentrations should be measured to the nearest 0.1 ug/L.
